Step 1: The Command Originates from Your Laptop

The process begins on your laptop or PC. When you send a serial command, it travels from your computer's USB port through a USB-to-serial adapter cable, ending in a DB9 connector.

Here is a diagram of your hardware setup and how the serial command flows.

Step 2: The Command Reaches the PAX L920BE Dock

The DB9 connector from the previous step is plugged into a custom DB9-to-RJ45 cable. This cable then connects to the RS232 port on the PAX L920BE dock. The dock is also connected to the internet via an Ethernet cable and receives power from a micro-USB cable.

Step 3: The Dock Transmits the Command Wirelessly to the PAX A920

Finally, the PAX L920BE dock acts as a wireless access point. It generates a Wi-Fi SSID and/or uses Bluetooth to wirelessly transmit the transaction request to your handheld PAX A920 terminal. The process works in reverse when the A920 sends data back to your laptop.
